

TITLE: **HYPERSENSITIVE RESPONSE ELICITOR
FROM *ERWINIA AMYLOVORA*, ITS USE,
AND ENCODING GENE**

INVENTORS: **Adam J. Bogdanove, Jihyun Francis Kim,
Zhong-Min Wei, and Steven V. Beer**

DOCKET NO.: **19603-1661 (CRF D-2098A)**

19603-1661 (CRF D-2098A)

**HYPERSENSITIVE RESPONSE ELICITOR FROM
ERWINIA AMYLOVORA, ITS USE, AND ENCODING GENE**

FWA This application claims benefit of U.S. Provisional Patent Application
60/055,106
5 Serial No. 60/055,105, filed August 4, 1997.

FIELD OF THE INVENTION

The present invention relates to a hypersensitive response elicitor from
10 *Erwinia amylovora*, its use, and encoding gene.

BACKGROUND OF THE INVENTION

Interactions between bacterial pathogens and their plant hosts generally
15 fall into two categories: (1) compatible (pathogen-host), leading to intercellular
bacterial growth, symptom development, and disease development in the host plant;
and (2) incompatible (pathogen-nonhost), resulting in the hypersensitive response, a
particular type of incompatible interaction occurring, without progressive disease
symptoms. During compatible interactions on host plants, bacterial populations
20 increase dramatically and progressive symptoms occur. During incompatible
interactions, bacterial populations do not increase, and progressive symptoms do not
occur.

The hypersensitive response ("HR") is a rapid, localized necrosis that
is associated with the active defense of plants against many pathogens (Kiraly, Z.,
25 "Defenses Triggered by the Invader: Hypersensitivity," pages 201-224 in: Plant
Disease: An Advanced Treatise, Vol. 5, J.G. Horsfall and E.B. Cowling, ed.
Academic Press New York (1980); Klement, Z., "Hypersensitivity," pages 149-177
in: Phytopathogenic Prokaryotes, Vol. 2, M.S. Mount and G.H. Lacy, ed. Academic
Press, New York (1982)). The hypersensitive response elicited by bacteria is readily
30 observed as a tissue collapse if high concentrations ($\geq 10^7$ cells/ml) of a limited
host-range pathogen like *Pseudomonas syringae* or *Erwinia amylovora* are infiltrated
into the leaves of nonhost plants (necrosis occurs only in isolated plant cells at lower
levels of inoculum) (Klement, Z., "Rapid Detection of Pathogenicity of
Phytopathogenic Pseudomonads," Nature 199:299-300; Klement, et al.,

“Hypersensitive Reaction Induced by Phytopathogenic Bacteria in the Tobacco Leaf,” Phytopathology 54:474-477 (1963); Turner, et al., “The Quantitative Relation Between Plant and Bacterial Cells Involved in the Hypersensitive Reaction,” Phytopathology 64:885-890 (1974); Klement, Z., “Hypersensitivity,” pages 149-177 in Phytopathogenic Prokaryotes, Vol. 2., M.S. Mount and G.H. Lacy, ed. Academic Press, New York (1982)). The capacities to elicit the hypersensitive response in a nonhost and be pathogenic in a host appear linked. As noted by Klement, Z., “Hypersensitivity,” pages 149-177 in Phytopathogenic Prokaryotes, Vol. 2., M.S. Mount and G.H. Lacy, ed. Academic Press, New York, these pathogens also cause physiologically similar, albeit delayed, necroses in their interactions with compatible hosts. Furthermore, the ability to produce the hypersensitive response or pathogenesis is dependent on a common set of genes, denoted *hrp* (Lindgren, P.B., et al., “Gene Cluster of *Pseudomonas syringae* pv. ‘phaseolicola’ Controls Pathogenicity of Bean Plants and Hypersensitivity on Nonhost Plants,” J. Bacteriol. 168:512-22 (1986); Willis, D.K., et al., “*hrp* Genes of Phytopathogenic Bacteria,” Mol. Plant-Microbe Interact. 4:132-138 (1991)). Consequently, the hypersensitive response may hold clues to both the nature of plant defense and the basis for bacterial pathogenicity.

The *hrp* genes are widespread in gram-negative plant pathogens, where they are clustered, conserved, and in some cases interchangeable (Willis, D.K., et al., “*hrp* Genes of Phytopathogenic Bacteria,” Mol. Plant-Microbe Interact. 4:132-138 (1991); Bonas, U., “*hrp* Genes of Phytopathogenic Bacteria,” pages 79-98 in: Current Topics in Microbiology and Immunology: Bacterial Pathogenesis of Plants and Animals - Molecular and Cellular Mechanisms, J.L. Dangel, ed. Springer-Verlag, Berlin (1994)). Several *hrp* genes encode components of a protein secretion pathway similar to one used by *Yersinia*, *Shigella*, and *Salmonella* spp. to secrete proteins essential in animal diseases (Van Gijsegem, et al., “Evolutionary Conservation of Pathogenicity Determinants Among Plant and Animal Pathogenic Bacteria,” Trends Microbiol. 1:175-180 (1993)). In *E. amylovora*, *P. syringae*, and *P. solanacearum*, *hrp* genes have been shown to control the production and secretion of glycine-rich, protein elicitors of the hypersensitive response (He, S.Y., et al. “*Pseudomonas Syringae* pv. *Syringae* Harpin_{PSS}: a Protein that is Secreted via the Hrp Pathway and Elicits the Hypersensitive Response in Plants,” Cell 73:1255-1266 (1993), Wei, Z.-H.,

et al., "HrpI of *Erwinia amylovora* Functions in Secretion of Harpin and is a Member of a New Protein Family," J. Bacteriol. 175:7958-7967 (1993); Arlat, M. et al. "PopA1, a Protein Which Induces a Hypersensitive-like Response on Specific Petunia Genotypes, is Secreted via the Hrp Pathway of *Pseudomonas solanacearum*," EMBO J. 13:543-553 (1994)).

5 The first of these proteins was discovered in *E. amylovora* Ea321, a bacterium that causes fire blight of rosaceous plants, and was designated harpin (Wei, Z.-M., et al., "Harpin, Elicitor of the Hypersensitive Response Produced by the Plant Pathogen *Erwinia amylovora*," Science 257:85-88 (1992)). Mutations in the encoding
10 *hrpN* gene revealed that the hypersensitive response elicitor is required for *E. amylovora* to elicit a hypersensitive response in nonhost tobacco leaves and incite disease symptoms in highly susceptible pear fruit. The *P. solanacearum* GMI1000 PopA1 protein has similar physical properties and also elicits the hypersensitive response in leaves of tobacco, which is not a host of that strain (Arlat, et al. "PopA1, a
15 Protein Which Induces a Hypersensitive-like Response on Specific Petunia Genotypes, is Secreted via the Hrp Pathway of *Pseudomonas solanacearum*," EMBO J. 13:543-53 (1994)). However, *P. solanacearum popA* mutants still elicit the hypersensitive response in tobacco and incite disease in tomato. Thus, the role of these glycine-rich hypersensitive response elicitors can vary widely among
20 gram-negative plant pathogens.

Other plant pathogenic hypersensitive response elicitors have been isolated and their encoding genes have been cloned and sequenced. These include: *Erwinia chrysanthemi* (Bauer, et. al., "*Erwinia chrysanthemi* Harpin_{Ech}: Soft-Rot Pathogenesis," MPMI 8(4): 484-91 (1995)); *Erwinia carotovora* (Cui, et. al., "The
25 RsmA⁻ Mutants of *Erwinia carotovora* subsp. *carotovora* Strain Ecc71 Overexpress *hrpN*_{Ecc} and Elicit a Hypersensitive Reaction-like Response in Tobacco Leaves," MPMI 9(7): 565-73 (1996)); *Erwinia stewartii* (Ahmad, et. al., "Harpin is not Necessary for the Pathogenicity of *Erwinia stewartii* on Maize," 8th Int'l. Cong. Molec. Plant-Microb. Inter. July 14-19, 1996 and Ahmad, et. al., "Harpin is not
30 Necessary for the Pathogenicity of *Erwinia stewartii* on Maize," Ann. Mtg. Am. Phytopath. Soc. July 27-31, 1996); and *Pseudomonas syringae* pv. *syringae* (WO 94/26782 to Cornell Research Foundation, Inc.).

The present invention is a further advance in the effort to identify, clone, and sequence hypersensitive response elicitor proteins or polypeptides from plant pathogens.

5

SUMMARY OF THE INVENTION

The present invention is directed to an isolated protein or polypeptide which elicits a hypersensitive response in plants as well as an isolated DNA molecule which encodes the hypersensitive response eliciting protein or polypeptide.

10

The hypersensitive response eliciting protein or polypeptide can be used to impart disease resistance to plants, to enhance plant growth, and/or to control insects. This involves applying the hypersensitive response elicitor protein or polypeptide in a non-infectious form to plants or plant seeds under conditions effective to impart disease resistance, to enhance plant growth, and/or to control

15

insects on plants or plants grown from the plant seeds.

20

As an alternative to applying the hypersensitive response elicitor protein or polypeptide to plants or plant seeds in order to impart disease resistance, to enhance plant growth, and/or to control insects on plants, transgenic plants or plant seeds can be utilized. When utilizing transgenic plants, this involves providing a transgenic plant transformed with a DNA molecule encoding a hypersensitive response elicitor protein or polypeptide and growing the plant under conditions effective to impart disease resistance, to enhance plant growth, and/or to control insects in the plants or plants grown from the plant seeds. Alternatively, a transgenic plant seed transformed with the DNA molecule encoding a hypersensitive response elicitor protein or polypeptide can be provided and planted in soil. A plant is then propagated under conditions effective to impart disease resistance, to enhance plant growth, and/or to control insects on plants or plants grown from the plant seeds.

25

BRIEF DESCRIPTION OF THE DRAWINGS

30

Figures 1A-D show mutagenesis, complementation and heterologous expression constructs, and homology with and complementation of mutants by the *avrE* locus of *P. syringae* for the *dspE* operon of *E. amylovora*. Dashed boxes are

uncharacterized ORFs; a filled triangle indicates a *hrp* (i.e. hypersensitive response elicitor encoding gene); box is a regulatory sequence that preceeds many *hrp* genes; and an open triangle indicates another promoter. Thick lines delineate the DNA for which sequence was accessioned. Figure 1A shows the *dsp/hrp* gene cluster of

5 *E. amylovora* in pCPP430. Operon names and types of proteins encoded are indicated at the top. B, *Bam*HI; E, *Eco*RI; H, *Hind*III. Half-arrows indicate internal promoters without similarity to the *hrp* box consensus. Figure 1B shows the region downstream of *hrpN* containing the *dspE* operon. Circles mark deletion mutations and representative transposon insertions: black, non-pathogenic and HR⁺ (i.e.

10 hypersensitive response eliciting) or HR reduced (*dsp*); gray, reduced virulence and HR; white, wild-type. T104 lies within the area marked by the dashed double arrow. K, *Tn5miniKm*; P, *Tn5phoA*; T, *Tn10tet*^r; Δ, deletion mutation. The gray box is A/T-rich DNA. Figure 1C shows the clones and subclones of the *dspE* operon. Plasmid designations are indicated at the left, and vector-borne promoters at the right.

15 Restriction sites used for subcloning not shown above are shown in parentheses. A "+" aligned with a circle representing a mutation in B indicates that the subclone complements that mutation. Figure 1D shows the *avrE* locus (transcription units III and IV) of *P. syringae* pv. tomato DC3000 in pCPP2357. Percent amino acid identity of the predicted proteins AvrE and AvrF to DspE and DspF, respectively, are

20 indicated. Black rectangles are transcriptional terminators (inverted repeats). Complementation of mutations shown in Figure 1B are depicted as in Figure 1C, above.

Figure 2 shows the expression of the full-length and the N-terminal half of DspE in recombinant *E. coli* DH5α. Lysates of cells carrying either

25 pCPP1259, containing the entire *dspE* operon (lane A); pCPP50, the cloning vector (lane B); or pCPP1244, containing only the 5' half of the *dspE* gene (lane C), were subjected to SDS-PAGE followed by Coomassie staining. Bands corresponding to DspE (lane A) and the N-terminal half of DspE (lane C) are marked by arrows. Migration of molecular weight markers is indicated on the left.

30 Figures 3A-D show the role of *dspE* in pathogenicity and HR elicitation. Figure 3A shows immature pear fruit 4 days after inoculation with (left to right) strains Ea321, Ea321*dspE*Δ1554, or Ea321*dspE*Δ1554 harboring the 5' half of

dspE on pCPP1237. Figure 3B shows Norchief soybean leaf 24 hr after infiltration with (1) Ea321, (2) Ea321*dspE*Δ1554, (3) Ea321*hrpN::Tn5* (Wei, et al., Science, 257:85-88 (1992), which is hereby incorporated by reference), and (4) Ea321*hrpL::Tn5* (Wei, et al., J. Bacteriol., 177:6201-10 (1995), which is hereby incorporated by reference). Figure 3C shows a tobacco leaf 48 hr after infiltration with parallel dilution series of suspensions of strains (left) Ea321 and (right) Ea321*dspE*Δ1554. The concentrations infiltrated (top to bottom) are 1×10^{10} , 1×10^9 , 5×10^8 , and 5×10^7 cfu/ml. Figure 3D is like Figure 3C except the more virulent strain Ea273 and corresponding mutant Ea273*dspE*Δ1554 were used, and concentrations ranged from 5×10^9 to 5×10^5 cfu/ml in log increments.

Figure 4 shows the expression of a promoterless GUS construct fused to *dspE* in *E. amylovora* Ea273. Ea273 and Ea273*dspE::uidA* (a merodiploid containing both a wild-type *dspE* and a truncated *dspE* fused to the *uidA* gene; black bars) were grown in LB or Hrp MM, or inoculated to immature pear fruit. Ea273*dspE::uidAhrpL::Tn5* (dark gray bar) and Ea273*hrcV::Tn5uidA* (light gray bar) were also grown in *hrp* MM. Values shown represent means of triplicate samples normalized for bacterial cell concentration. Standard deviations are represented by lines extending from each bar. The mean values for three samples of Ea273 in each assay were subtracted from, and standard deviations added to, the corresponding values obtained for the other strains.

Figures 5A-C show the transgeneric avirulence function of the *dspE* operon and complementation of a *dspE* mutant with the *avrE* locus. Norchief soybean leaves were either (See Figure 5A) infiltrated with 1×10^8 cfu/ml suspensions of (left) *P. syringae* pv. *glycinea* race 4 carrying pCPP1250 (containing the *dspE* operon) or (right) pML 122 (the cloning vector) and photographed after 24 hr at room temperature or (See Figure 5B) infiltrated with 8×10^5 cfu/ml suspensions of the same strains and photographed after seven days at 22° C and high relative humidity. Tissue collapse is apparent on both leaves where the strain carrying pCPP1250 was infiltrated. On the leaf incubated for seven days, chlorosis extending beyond the infiltrated area, typical of disease, is apparent on the half infiltrated with the strain carrying the vector only. The dark section on the side of the leaf infiltrated with the strain carrying pCPP1250 is a shadow caused by a buckle in the leaf. Figure 5C

shows pear halves inoculated with (left to right) Ea321, Ea321*dspE*Δ1521(pCPP2357, containing the *avrE* locus), or Ea321*dspE*Δ1521(pCPP2357*avrE::Tn5uidA*) and photographed after seven days. Although symptoms are greatly reduced relative to wild type, necrosis is apparent around and drops of ooze can be seen within the well of the fruit inoculated with the *dspE* strain carrying the intact *avrE* locus. The fruit inoculated with the *dspE* strain carrying a disrupted clone of *avrE* is symptomless.

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to an isolated DNA molecule having a nucleotide sequence of SEQ. ID. No. 1 as follows:

This protein or polypeptide is about 16 kDa and has a pI of 4.45.

Fragments of the above hypersensitive response elicitor polypeptide or protein are encompassed by the present invention.

5 Suitable fragments can be produced by several means. In the first, subclones of the gene encoding the elicitor protein of the present invention are produced by conventional molecular genetic manipulation by subcloning gene fragments. The subclones then are expressed *in vitro* or *in vivo* in bacterial cells to yield a smaller protein or peptide that can be tested for elicitor activity according to
10 the procedure described below.

As an alternative, fragments of an elicitor protein can be produced by digestion of a full-length elicitor protein with proteolytic enzymes like chymotrypsin or *Staphylococcus* proteinase A, or trypsin. Different proteolytic enzymes are likely to cleave elicitor proteins at different sites based on the amino acid sequence of the
15 elicitor protein. Some of the fragments that result from proteolysis may be active elicitors of resistance.

In another approach, based on knowledge of the primary structure of the protein, fragments of the elicitor protein gene may be synthesized by using the PCR technique together with specific sets of primers chosen to represent particular
20 portions of the protein. These then would be cloned into an appropriate vector for increased expression of a truncated peptide or protein.

Chemical synthesis can also be used to make suitable fragments. Such a synthesis is carried out using known amino acid sequences for the elicitor being produced. Alternatively, subjecting a full length elicitor to high temperatures and
25 pressures will produce fragments. These fragments can then be separated by conventional procedures (e.g., chromatography, SDS-PAGE).

Variants may also (or alternatively) be modified by, for example, the deletion or addition of amino acids that have minimal influence on the properties, secondary structure and hydrophobic nature of the polypeptide. For example, a
30 polypeptide may be conjugated to a signal (or leader) sequence at the N-terminal end of the protein which co-translationally or post-translationally directs transfer of the protein. The polypeptide may also be conjugated to a linker or other sequence for ease of synthesis, purification, or identification of the polypeptide.

Suitable DNA molecules are those that hybridize to a DNA molecule comprising a nucleotide sequence of SEQ. ID. Nos. 1 and 3, under stringent conditions. An example of suitable high stringency conditions is when hybridization is carried out at 65°C for 20 hours in a medium containing 1M NaCl, 50 mM Tris-HCl, pH 7.4, 10 mM EDTA, 0.1% sodium dodecyl sulfate, 0.2% ficoll, 0.2% polyvinylpyrrolidone, 0.2% bovine serum albumin, 50 µm g/ml *E. coli* DNA. However, any DNA molecules hybridizing to a DNA molecule comprising the nucleotide sequences of SEQ. ID. Nos. 1 and 3, under such stringent conditions must not be identical to the nucleic acids encoding the hypersensitive response elicitor proteins or polypeptides of *E. amylovora* (as disclosed by Wei, Z.-M., et al, "Harpin, Elicitor of the Hypersensitive Response Produced by the Plant Pathogen *Erwinia amylovora*," Science 257:85-88 (1992), which is hereby incorporated by reference), *Erwinia chrysanthemi* (as disclosed by Bauer, et. al., "*Erwinia chrysanthemi* Harpin_{Ech}: Soft-Rot Pathogenesis," MPMI 8(4): 484-91 (1995), which is hereby incorporated by reference), *Erwinia carotovora* (as disclosed by Cui, et. al., "The RsmA⁻ Mutants of *Erwinia carotovora* subsp. *carotovora* Strain Ecc71 Overexpress *hrpN*_{Ecc} and Elicit a Hypersensitive Reaction-like Response in Tobacco Leaves," MPMI 9(7): 565-73 (1996), which is hereby incorporated by reference), *Erwinia stewartii* (as disclosed by Ahmad, et. al., "Harpin is not Necessary for the Pathogenicity of *Erwinia stewartii* on Maize," 8th Int'l. Cong. Molec. Plant-Microb. Inter. July 14-19, 1996 and Ahmad, et. al., "Harpin is not Necessary for the Pathogenicity of *Erwinia stewartii* on Maize," Ann. Mtg. Am. Phytopath. Soc. July 27-31, 1996), which are hereby incorporated by reference), and *Pseudomonas syringae* pv. *syringae* (WO 94/26782 to Cornell Research Foundation, Inc., which is hereby incorporated by reference).

The protein or polypeptide of the present invention is preferably produced in purified form (preferably at least about 80%, more preferably 90%, pure) by conventional techniques. Typically, the protein or polypeptide of the present invention is secreted into the growth medium of recombinant host cells. Alternatively, the protein or polypeptide of the present invention is produced but not secreted into growth medium. In such cases, to isolate the protein, the host cell (e.g., *E. coli*) carrying a recombinant plasmid is propagated, lysed by sonication, heat, or

chemical treatment, and the homogenate is centrifuged to remove bacterial debris. The supernatant is then subjected to sequential ammonium sulfate precipitation. The fraction containing the polypeptide or protein of the present invention is subjected to gel filtration in an appropriately sized dextran or polyacrylamide column to separate the proteins. If necessary, the protein fraction may be further purified by HPLC.

The DNA molecule encoding the hypersensitive response elicitor polypeptide or protein can be incorporated in cells using conventional recombinant DNA technology. Generally, this involves inserting the DNA molecule into an expression system to which the DNA molecule is heterologous (i.e. not normally present). The heterologous DNA molecule is inserted into the expression system or vector in proper sense orientation and correct reading frame. The vector contains the necessary elements for the transcription and translation of the inserted protein-coding sequences.

U.S. Patent No. 4,237,224 to Cohen and Boyer, which is hereby incorporated by reference, describes the production of expression systems in the form of recombinant plasmids using restriction enzyme cleavage and ligation with DNA ligase. These recombinant plasmids are then introduced by means of transformation and replicated in unicellular cultures including procaryotic organisms and eucaryotic cells grown in tissue culture.

Recombinant genes may also be introduced into viruses, such as vaccina virus. Recombinant viruses can be generated by transfection of plasmids into cells infected with virus.

Suitable vectors include, but are not limited to, the following viral vectors such as lambda vector system gt11, gt WES.tB, Charon 4, and plasmid vectors such as pBR322, pBR325, pACYC177, pACYC1084, pUC8, pUC9, pUC18, pUC19, pLG339, pR290, pKC37, pKC101, SV 40, pBluescript II SK +/- or KS +/- (see "Stratagene Cloning Systems" Catalog (1993) from Stratagene, La Jolla, Calif, which is hereby incorporated by reference), pQE, pIH821, pGEX, pET series (see F.W. Studier et. al., "Use of T7 RNA Polymerase to Direct Expression of Cloned Genes," Gene Expression Technology vol. 185 (1990), which is hereby incorporated by reference), and any derivatives thereof. Recombinant molecules can be introduced into cells via transformation, particularly transduction, conjugation, mobilization, or

electroporation. The DNA sequences are cloned into the vector using standard cloning procedures in the art, as described by Sambrook et al., Molecular Cloning: A Laboratory Manual, Cold Springs Laboratory, Cold Springs Harbor, New York (1989), which is hereby incorporated by reference.

5 A variety of host-vector systems may be utilized to express the protein-encoding sequence(s). Primarily, the vector system must be compatible with the host cell used. Host-vector systems include but are not limited to the following: bacteria transformed with bacteriophage DNA, plasmid DNA, or cosmid DNA; microorganisms such as yeast containing yeast vectors; mammalian cell systems
10 infected with virus (e.g., vaccinia virus, adenovirus, etc.); insect cell systems infected with virus (e.g., baculovirus); and plant cells infected by bacteria. The expression elements of these vectors vary in their strength and specificities. Depending upon the host-vector system utilized, any one of a number of suitable transcription and translation elements can be used.

15 Different genetic signals and processing events control many levels of gene expression (e.g., DNA transcription and messenger RNA (mRNA) translation).

 Transcription of DNA is dependent upon the presence of a promotor which is a DNA sequence that directs the binding of RNA polymerase and thereby promotes mRNA synthesis. The DNA sequences of eucaryotic promoters differ from
20 those of procaryotic promoters. Furthermore, eucaryotic promoters and accompanying genetic signals may not be recognized in or may not function in a procaryotic system, and, further, procaryotic promoters are not recognized and do not function in eucaryotic cells.

 Similarly, translation of mRNA in procaryotes depends upon
25 the presence of the proper procaryotic signals which differ from those of eucaryotes. Efficient translation of mRNA in procaryotes requires a ribosome binding site called the Shine-Dalgarno ("SD") sequence on the mRNA. This sequence is a short nucleotide sequence of mRNA that is located before the start codon, usually AUG, which encodes the amino-terminal methionine of the protein. The SD sequences are
30 complementary to the 3'-end of the 16S rRNA (ribosomal RNA) and probably promote binding of mRNA to ribosomes by duplexing with the rRNA to allow correct positioning of the ribosome. For a review on maximizing gene expression, see

Roberts and Lauer, Methods in Enzymology, 68:473 (1979), which is hereby incorporated by reference.

Promoters vary in their "strength" (i.e. their ability to promote transcription). For the purposes of expressing a cloned gene, it is desirable to use strong promoters in order to obtain a high level of transcription and, hence, expression of the gene. Depending upon the host cell system utilized, any one of a number of suitable promoters may be used. For instance, when cloning in *E. coli*, its bacteriophages, or plasmids, promoters such as the T7 phage promoter, *lac* promoter, *trp* promoter, *recA* promoter, ribosomal RNA promoter, the P_R and P_L promoters of coliphage lambda and others, including but not limited, to *lacUV5*, *ompF*, *bla*, *lpp*, and the like, may be used to direct high levels of transcription of adjacent DNA segments. Additionally, a hybrid *trp-lacUV5 (tac)* promoter or other *E. coli* promoters produced by recombinant DNA or other synthetic DNA techniques may be used to provide for transcription of the inserted gene.

Bacterial host cell strains and expression vectors may be chosen which inhibit the action of the promoter unless specifically induced. In certain operations, the addition of specific inducers is necessary for efficient transcription of the inserted DNA. For example, the *lac* operon is induced by the addition of lactose or IPTG (isopropylthio-beta-D-galactoside). A variety of other operons, such as *trp*, *pro*, etc., are under different controls.

Specific initiation signals are also required for efficient gene transcription and translation in procaryotic cells. These transcription and translation initiation signals may vary in "strength" as measured by the quantity of gene specific messenger RNA and protein synthesized, respectively. The DNA expression vector, which contains a promoter, may also contain any combination of various "strong" transcription and/or translation initiation signals. For instance, efficient translation in *E. coli* requires an SD sequence about 7-9 bases 5' to the initiation codon ("ATG") to provide a ribosome binding site. Thus, any SD-ATG combination that can be utilized by host cell ribosomes may be employed. Such combinations include but are not limited to the SD-ATG combination from the *cro* gene or the *N* gene of coliphage lambda, or from the *E. coli* tryptophan E, D, C, B or A genes. Additionally, any SD-

ATG combination produced by recombinant DNA or other techniques involving incorporation of synthetic nucleotides may be used.

Once the isolated DNA molecule encoding the hypersensitive response elicitor polypeptide or protein has been cloned into an expression system, it is ready
5 to be incorporated into a host cell. Such incorporation can be carried out by the various forms of transformation noted above, depending upon the vector/host cell system. Suitable host cells include, but are not limited to, bacteria, virus, yeast, mammalian cells, insect, plant, and the like.

The present invention further relates to methods of imparting disease
10 resistance to plants, enhancing plant growth, and/or effecting insect control for plants. These methods involve applying a hypersensitive response elicitor polypeptide or protein in a non-infectious form to all or part of a plant or a plant seed under conditions where the polypeptide or protein contacts all or part of the cells of the plant or plant seed. Alternatively, the hypersensitive response elicitor protein or
15 polypeptide can be applied to plants such that seeds recovered from such plants themselves are able to impart disease resistance in plants, to enhance plant growth, and/or to effect insect control.

As an alternative to applying a hypersensitive response elicitor polypeptide or protein to plants or plant seeds in order to impart disease resistance in
20 plants, to effect plant growth, and/or to control insects on the plants or plants grown from the seeds, transgenic plants or plant seeds can be utilized. When utilizing transgenic plants, this involves providing a transgenic plant transformed with a DNA molecule encoding a hypersensitive response elicitor polypeptide or protein and growing the plant under conditions effective to permit that DNA molecule to impart
25 disease resistance to plants, to enhance plant growth, and/or to control insects. Alternatively, a transgenic plant seed transformed with a DNA molecule encoding a hypersensitive response elicitor polypeptide or protein can be provided and planted in soil. A plant is then propagated from the planted seed under conditions effective to permit that DNA molecule to impart disease resistance to plants, to enhance plant
30 growth, and/or to control insects.

The embodiment of the present invention where the hypersensitive response elicitor polypeptide or protein is applied to the plant or plant seed can be

carried out in a number of ways, including: 1) application of an isolated elicitor polypeptide or protein; 2) application of bacteria which do not cause disease and are transformed with genes encoding a hypersensitive response elicitor polypeptide or protein; and 3) application of bacteria which cause disease in some plant species (but not in those to which they are applied) and naturally contain a gene encoding the hypersensitive response elicitor polypeptide or protein.

In one embodiment of the present invention, the hypersensitive response elicitor polypeptide or protein of the present invention can be isolated from *Erwinia amylovora* as described in the Examples *infra*. Preferably, however, the isolated hypersensitive response elicitor polypeptide or protein of the present invention is produced recombinantly and purified as described *supra*.

In other embodiments of the present invention, the hypersensitive response elicitor polypeptide or protein of the present invention can be applied to plants or plant seeds by applying bacteria containing genes encoding the hypersensitive response elicitor polypeptide or protein. Such bacteria must be capable of secreting or exporting the polypeptide or protein so that the elicitor can contact plant or plant seed cells. In these embodiments, the hypersensitive response elicitor polypeptide or protein is produced by the bacteria *in planta* or on seeds or just prior to introduction of the bacteria to the plants or plant seeds.

In one embodiment of the bacterial application mode of the present invention, the bacteria do not cause the disease and have been transformed (e.g., recombinantly) with genes encoding a hypersensitive response elicitor polypeptide or protein. For example, *E. coli*, which does not elicit a hypersensitive response in plants, can be transformed with genes encoding a hypersensitive response elicitor polypeptide or protein and then applied to plants. Bacterial species other than *E. coli* can also be used in this embodiment of the present invention.

In another embodiment of the bacterial application mode of the present invention, the bacteria do cause disease and naturally contain a gene encoding a hypersensitive response elicitor polypeptide or protein. Examples of such bacteria are noted above. However, in this embodiment, these bacteria are applied to plants or their seeds which are not susceptible to the disease carried by the bacteria. For example, *Erwinia amylovora* causes disease in apple or pear but not in tomato.

However, such bacteria will elicit a hypersensitive response in tomato. Accordingly, in accordance with this embodiment of the present invention, *Erwinia amylovora* can be applied to tomato plants or seeds to enhance growth without causing disease in that species.

5 The method of the present invention can be utilized to treat a wide variety of plants or their seeds to impart disease resistance, enhance growth, and/or control insects. Suitable plants include dicots and monocots. More particularly, useful crop plants can include: alfalfa, rice, wheat, barley, rye, cotton, sunflower, peanut, corn, potato, sweet potato, bean, pea, chicory, lettuce, endive, cabbage,
10 brussel sprout, beet, parsnip, turnip, cauliflower, broccoli, turnip, radish, spinach, onion, garlic, eggplant, pepper, celery, carrot, squash, pumpkin, zucchini, cucumber, apple, pear, melon, citrus, strawberry, grape, raspberry, pineapple, soybean, tobacco, tomato, sorghum, and sugarcane. Examples of suitable ornamental plants are:
15 *Arabidopsis thaliana*, *Saintpaulia*, petunia, pelargonium, poinsettia, chrysanthemum, carnation, and zinnia.

 With regard to the use of the hypersensitive response elicitor protein or polypeptide of the present invention in imparting disease resistance, absolute immunity against infection may not be conferred, but the severity of the disease is reduced and symptom development is delayed. Lesion number, lesion size, and
20 extent of sporulation of fungal pathogens are all decreased. This method of imparting disease resistance has the potential for treating previously untreatable diseases, treating diseases systemically which might not be treated separately due to cost, and avoiding the use of infectious agents or environmentally harmful materials.

 The method of imparting pathogen resistance to plants in accordance
25 with the present invention is useful in imparting resistance to a wide variety of pathogens including viruses, bacteria, and fungi. Resistance, *inter alia*, to the following viruses can be achieved by the method of the present invention: *Tobacco mosaic virus* and *Tomato mosaic virus*. Resistance, *inter alia*, to the following bacteria can also be imparted to plants in accordance with present invention:
30 *Pseudomonas solanacearum*, *Pseudomonas syringae* pv. *tabaci*, and *Xanthomonas campestris* pv. *pelargonii*. Plants can be made resistant, *inter alia*, to the following

fungi by use of the method of the present invention: *Fusarium oxysporum* and *Phytophthora infestans*.

With regard to the use of the hypersensitive response elicitor protein or polypeptide of the present invention to enhance plant growth, various forms of plant growth enhancement or promotion can be achieved. This can occur as early as when plant growth begins from seeds or later in the life of a plant. For example, plant growth according to the present invention encompasses greater yield, increased quantity of seeds produced, increased percentage of seeds germinated, increased plant size, greater biomass, more and bigger fruit, earlier fruit coloration, and earlier fruit and plant maturation. As a result, the present invention provides significant economic benefit to growers. For example, early germination and early maturation permit crops to be grown in areas where short growing seasons would otherwise preclude their growth in that locale. Increased percentage of seed germination results in improved crop stands and more efficient seed use. Greater yield, increased size, and enhanced biomass production allow greater revenue generation from a given plot of land.

Another aspect of the present invention is directed to effecting any form of insect control for plants. For example, insect control according to the present invention encompasses preventing insects from contacting plants to which the hypersensitive response elicitor has been applied, preventing direct insect damage to plants by feeding injury, causing insects to depart from such plants, killing insects proximate to such plants, interfering with insect larval feeding on such plants, preventing insects from colonizing host plants, preventing colonizing insects from releasing phytotoxins, etc. The present invention also prevents subsequent disease damage to plants resulting from insect infection.

The present invention is effective against a wide variety of insects. European corn borer is a major pest of corn (dent and sweet corn) but also feeds on over 200 plant species including green, wax, and lima beans and edible soybeans, peppers, potato, and tomato plus many weed species. Additional insect larval feeding pests which damage a wide variety of vegetable crops include the following: beet armyworm, cabbage looper, corn ear worm, fall armyworm, diamondback moth, cabbage root maggot, onion maggot, seed corn maggot, pickleworm (melonworm), pepper maggot, and tomato pinworm. Collectively, this group of insect pests

represents the most economically important group of pests for vegetable production worldwide.

5 The method of the present invention involving application of the hypersensitive response elicitor polypeptide or protein can be carried out through a variety of procedures when all or part of the plant is treated, including leaves, stems, roots, propagules (e.g., cuttings), etc. This may (but need not) involve infiltration of the hypersensitive response elicitor polypeptide or protein into the plant. Suitable application methods include high or low pressure spraying, injection, and leaf abrasion proximate to when elicitor application takes place. When treating plant seeds, in accordance with the application embodiment of the present invention, the hypersensitive response elicitor protein or polypeptide can be applied by low or high pressure spraying, coating, immersion, or injection. Other suitable application procedures can be envisioned by those skilled in the art provided they are able to effect contact of the hypersensitive response elicitor polypeptide or protein with cells of the plant or plant seed. Once treated with the hypersensitive response elicitor of the present invention, the seeds can be planted in natural or artificial soil and cultivated using conventional procedures to produce plants. After plants have been propagated from seeds treated in accordance with the present invention, the plants may be treated with one or more applications of the hypersensitive response elicitor protein or polypeptide to impart disease resistance to plants, to enhance plant growth, and/or to control insects on the plants.

25 The hypersensitive response elicitor polypeptide or protein can be applied to plants or plant seeds in accordance with the present invention alone or in a mixture with other materials. Alternatively, the hypersensitive response elicitor polypeptide or protein can be applied separately to plants with other materials being applied at different times.

30 A composition suitable for treating plants or plant seeds in accordance with the application embodiment of the present invention contains a hypersensitive response elicitor polypeptide or protein in a carrier. Suitable carriers include water, aqueous solutions, slurries, or dry powders. In this embodiment, the composition contains greater than 500 nM hypersensitive response elicitor polypeptide or protein.

Although not required, this composition may contain additional additives including fertilizer, insecticide, fungicide, nematocide, and mixtures thereof. Suitable fertilizers include $(\text{NH}_4)_2\text{NO}_3$. An example of a suitable insecticide is Malathion. Useful fungicides include Captan.

5 Other suitable additives include buffering agents, wetting agents, coating agents, and abrading agents. These materials can be used to facilitate the process of the present invention. In addition, the hypersensitive response elicitor polypeptide or protein can be applied to plant seeds with other conventional seed formulation and treatment materials, including clays and polysaccharides.

10 In the alternative embodiment of the present invention involving the use of transgenic plants and transgenic seeds, a hypersensitive response elicitor polypeptide or protein need not be applied topically to the plants or seeds. Instead, transgenic plants transformed with a DNA molecule encoding a hypersensitive response elicitor polypeptide or protein are produced according to procedures well
15 known in the art.

The vector described above can be microinjected directly into plant cells by use of micropipettes to transfer mechanically the recombinant DNA. Crossway, Mol. Gen. Genetics, 202:179-85 (1985), which is hereby incorporated by reference. The genetic material may also be transferred into the plant cell using
20 polyethylene glycol. Krens, et al., Nature, 296:72-74 (1982), which is hereby incorporated by reference.

Another approach to transforming plant cells with a gene which imparts resistance to pathogens is particle bombardment (also known as biolistic transformation) of the host cell. This can be accomplished in one of several ways.
25 The first involves propelling inert or biologically active particles at cells. This technique is disclosed in U.S. Patent Nos. 4,945,050, 5,036,006, and 5,100,792, all to Sanford et al., which are hereby incorporated by reference. Generally, this procedure involves propelling inert or biologically active particles at the cells under conditions effective to penetrate the outer surface of the cell and to be incorporated within the
30 interior thereof. When inert particles are utilized, the vector can be introduced into the cell by coating the particles with the vector containing the heterologous DNA. Alternatively, the target cell can be surrounded by the vector so that the vector is

carried into the cell by the wake of the particle. Biologically active particles (e.g., dried bacterial cells containing the vector and heterologous DNA) can also be propelled into plant cells.

Yet another method of introduction is fusion of protoplasts with other entities, either minicells, cells, lysosomes or other fusible lipid-surfaced bodies. Fraley, et al., Proc. Natl. Acad. Sci. USA, 79:1859-63 (1982), which is hereby incorporated by reference.

The DNA molecule may also be introduced into the plant cells by electroporation. Fromm et al., Proc. Natl. Acad. Sci. USA, 82:5824 (1985), which is hereby incorporated by reference. In this technique, plant protoplasts are electroporated in the presence of plasmids containing the expression cassette. Electrical impulses of high field strength reversibly permeabilize biomembranes allowing the introduction of the plasmids. Electroporated plant protoplasts reform the cell wall, divide, and regenerate.

Another method of introducing the DNA molecule into plant cells is to infect a plant cell with *Agrobacterium tumefaciens* or *A. rhizogenes* previously transformed with the gene. Under appropriate conditions known in the art, the transformed plant cells are grown to form shoots or roots, and develop further into plants. Generally, this procedure involves inoculating the plant tissue with a suspension of bacteria and incubating the tissue for 48 to 72 hours on regeneration medium without antibiotics at 25-28°C.

Agrobacterium is a representative genus of the gram-negative family Rhizobiaceae. Its species are responsible for crown gall (*A. tumefaciens*) and hairy root disease (*A. rhizogenes*). The plant cells in crown gall tumors and hairy roots are induced to produce amino acid derivatives known as opines, which are catabolized only by the bacteria. The bacterial genes responsible for expression of opines are a convenient source of control elements for chimeric expression cassettes. In addition, assaying for the presence of opines can be used to identify transformed tissue.

Heterologous genetic sequences can be introduced into appropriate plant cells, by means of the Ti plasmid of *A. tumefaciens* or the Ri plasmid of *A. rhizogenes*. The Ti or Ri plasmid is transmitted to plant cells on infection by

Agrobacterium and is stably integrated into the plant genome. J. Schell, Science, 237:1176-83 (1987), which is hereby incorporated by reference.

After transformation, the transformed plant cells must be regenerated.

Plant regeneration from cultured protoplasts is described in Evans et al., Handbook of Plant Cell Cultures, Vol. 1: (MacMillan Publishing Co., New York, 1983); and Vasil I.R. (ed.), Cell Culture and Somatic Cell Genetics of Plants, Acad. Press, Orlando, Vol. I, 1984, and Vol. III (1986), which are hereby incorporated by reference.

It is known that practically all plants can be regenerated from cultured cells or tissues, including but not limited to, all major species of sugarcane, sugar beets, cotton, fruit trees, and legumes.

Means for regeneration vary from species to species of plants, but generally a suspension of transformed protoplasts or a petri plate containing transformed explants is first provided. Callus tissue is formed and shoots may be induced from callus and subsequently rooted. Alternatively, embryo formation can be induced in the callus tissue. These embryos germinate as natural embryos to form plants. The culture media will generally contain various amino acids and hormones, such as auxin and cytokinins. It is also advantageous to add glutamic acid and proline to the medium, especially for such species as corn and alfalfa. Efficient regeneration will depend on the medium, on the genotype, and on the history of the culture. If these three variables are controlled, then regeneration is usually reproducible and repeatable.

After the expression cassette is stably incorporated in transgenic plants, it can be transferred to other plants by sexual crossing. Any of a number of standard breeding techniques can be used, depending upon the species to be crossed.

Once transgenic plants of this type are produced, the plants themselves can be cultivated in accordance with conventional procedure with the presence of the gene encoding the hypersensitive response elicitor resulting in disease resistance, enhanced plant growth, and/or control of insects on the plant. Alternatively, transgenic seeds are recovered from the transgenic plants. These seeds can then be planted in the soil and cultivated using conventional procedures to produce transgenic plants. The transgenic plants are propagated from the planted transgenic seeds under

conditions effective to impart disease resistance to plants, to enhance plant growth, and/or to control insects. While not wishing to be bound by theory, such disease resistance, growth enhancement, and/or insect control may be RNA mediated or may result from expression of the elicitor polypeptide or protein.

5 When transgenic plants and plant seeds are used in accordance with the present invention, they additionally can be treated with the same materials as are used to treat the plants and seeds to which a hypersensitive response elicitor polypeptide or protein is applied. These other materials, including hypersensitive response elicitors, can be applied to the transgenic plants and plant seeds by the above-noted procedures, including high or low pressure spraying, injection, coating, and immersion. Similarly, 10 after plants have been propagated from the transgenic plant seeds, the plants may be treated with one or more applications of the hypersensitive response elicitor to impart disease resistance, enhance growth, and/or control insects. Such plants may also be treated with conventional plant treatment agents (e.g., insecticides, fertilizers, etc.).

15 Another aspect of the present invention is to utilize the subject elicitor proteins or polypeptides to design molecules that will inactivate, destroy, or bind to these proteins or polypeptides. Since these elicitors are found in plant pathogens, particularly *Erwinia amylovora*, the pathogens themselves can be neutralized by the designed molecules so that disease and/or hypersensitive response is prevented or 20 altered. Examples of disease preventing molecules are antibodies, such as monoclonal or polyclonal antibodies, raised against the elicitor proteins or polypeptides of the present invention or binding portions thereof. Other examples of disease preventing molecules include antibody fragments, half-antibodies, hybrid derivatives, probes, and other molecular constructs.

25 Monoclonal antibody production may be effected by techniques which are well-known in the art. Basically, the process involves first obtaining immune cells (lymphocytes) from the spleen of a mammal (e.g., mouse) which has been previously immunized, either *in vivo* or *in vitro*, with the antigen of interest (e.g., an elicitor protein or polypeptide of the present invention or binding portions thereof). 30 The antibody-secreting lymphocytes are then fused with (mouse) myeloma cells or transformed cells, which are capable of replicating indefinitely in cell culture, thereby producing an immortal, immunoglobulin-secreting cell line. The resulting fused cells,

or hybridomas, are cultured, and the resulting colonies screened for the production of the desired monoclonal antibodies. Colonies producing such antibodies are cloned, and grown either *in vivo* or *in vitro* to produce large quantities of antibody. A description of the theoretical basis and practical methodology of fusing such cells is set forth in Kohler and Milstein, Nature 256:495 (1975), which is hereby incorporated by reference.

Mammalian lymphocytes are immunized by *in vivo* immunization of the animal (e.g., a mouse) with the elicitor proteins or polypeptides of the present invention or binding portions thereof. Such immunizations are repeated as necessary at intervals of up to several weeks to obtain a sufficient titer of antibodies. Following the last antigen boost, the animals are sacrificed and spleen cells removed.

Fusion with mammalian myeloma cells or other fusion partners capable of replicating indefinitely in cell culture is effected by standard and well-known techniques, for example, by using polyethylene glycol ("PEG") or other fusing agents (See Milstein and Kohler, Eur. J. Immunol. 6:511 (1976), which is hereby incorporated by reference). This immortal cell line, which is preferably murine, but may also be derived from cells of other mammalian species, including but not limited to rats, is selected to be deficient in enzymes necessary for the utilization of certain nutrients, to be capable of rapid growth, and to have good fusion capability. Many such cell lines are known to those skilled in the art, and others are regularly described.

Procedures for raising polyclonal antibodies are also well known. Typically, such antibodies can be raised by administering the elicitor proteins or polypeptides of the present invention or binding portions thereof subcutaneously to New Zealand white rabbits which have first been bled to obtain pre-immune serum. The antigens can be injected at a total volume of 100 μ l per site at six different sites. Each injected material will contain synthetic surfactant adjuvant pluronic polyols, or pulverized acrylamide gel containing the protein or polypeptide after SDS-polyacrylamide gel electrophoresis. The rabbits are then bled two weeks after the first injection and periodically boosted with the same antigen three times every six weeks. A sample of serum is then collected 10 days after each boost. Polyclonal antibodies are then recovered from the serum by affinity chromatography using the

corresponding antigen to capture the antibody. Ultimately, the rabbits are euthenized with pentobarbital 150 mg/Kg IV. This and other procedures for raising polyclonal antibodies are disclosed in E. Harlow, et. al., editors, Antibodies: A Laboratory Manual (1988), which is hereby incorporated by reference.

5 In addition to utilizing whole antibodies, the processes of the present invention encompass use of binding portions of such antibodies. Such binding portions include Fab fragments, F(ab')₂ fragments, and Fv fragments. These antibody fragments can be made by conventional procedures, such as proteolytic fragmentation procedures, as described in J. Goding, Monoclonal Antibodies: Principles and
10 Practice, pp. 98-118 (N.Y. Academic Press 1983), which is hereby incorporated by reference.

Alternatively, the processes of the present invention can utilize probes or ligands found either in nature or prepared synthetically by recombinant DNA procedures or other biological or molecular procedures. Suitable probes or ligands
15 are molecules which bind to the elicitor proteins or polypeptides of the present invention or binding portions thereof.

Avirulence (*avr*) genes (see Vivian, A., et al, Microbiology, 143:693-704 (1997); Leach, J. E., et al., Annu. Rev. Phytopathol., 34:153-179 (1996); Dangl, J. L. "Bacterial Pathogenesis of Plants and Animals: Molecular and Cellular
20 Mechanisms," in Current Topics in Microbiology and Immunology, Dangl, J. L., ed. (Springer, Berlin), Vol. 192, pp. 99-118 (1994), which are hereby incorporated by reference) generate signals that trigger defense responses leading to disease resistance in plants with corresponding resistance (*R*) genes. Typically, *avr* genes are isolated by expressing a cosmid library from one pathogen in another pathogen and screening
25 for narrowed host range. *avr* genes traditionally have been considered as negative determinants of host specificity at the race-cultivar level, but some, including the *avrE* locus from the bacterial speck pathogen *Pseudomonas syringae* pathovar (pv.) tomato (Kobayashi, D. Y., et al., Proc. Natl. Acad. Sci. USA, 86:157-61 (1989), which is hereby incorporated by reference), restrict host range at the pathovar-species or
30 species-species level (Whalen, M. C., et al., Proc. Natl. Acad. Sci. USA, 85:6743-47 (1988); Swarup, S., et al., Mol. Plant-Microbe Interact., 5:204-13 (1992), which are hereby incorporated by reference). Many *avr* genes, including *avrE*, are Hrp

regulated. *avrE* and *avrPphE* (Mansfield, J., et al., Mol. Plant-Microbe Interact., 7:726-39 (1994), which is hereby incorporated by reference) are physically linked to *hrp* genes.

When expressed *in trans*, the *avrE* locus renders *P. syringae* pv. glycinea, which causes bacterial blight of soybean, avirulent in all cultivars (Lorang, J. M., et al., Mol. Plant-Microbe Interact., 8:49-57 (1995), which is hereby incorporated by reference). The locus comprises two convergent transcription units, one preceded by a putative σ^{54} promoter and the other by a *hrp* box, a sequence found upstream of many *hrp* and *avr* genes that are positively regulated by the alternate sigma factor HrpL (Innes, R. W., et al., J. Bacteriol., 175:4859-69 (1993); Shen, H., et al., J. Bacteriol., 175:5916-24 (1993); Xiao, Y., et al., J. Bacteriol., 176:3089-91 (1994), which are hereby incorporated by reference). Expression of both transcripts require HrpL. The *avrE* locus contributes quantitatively to the virulence in tomato leaves of *P. syringae* pv. tomato strain PT23, but not of strain DC3000 (Lorang, J. M., et al., Mol. Plant-Microbe Interact., 8:49-57 (1995); Lorang, J. M., et al., Mol. Plant-Microbe Interact. 7:508-515 (1994)).

Thus, *avr* genes in plant pathogens bind to disease resistance genes in plants which are not susceptible to that pathogen. In view of the homology of the DNA molecules of the present invention to *avr* genes in plant pathogens, these DNA molecules can be used to identify corresponding plant disease resistance genes. Such identification is carried out by traditional plant breeding techniques in which a pathogen carrying the *avr* gene is inoculated to plants in screening to track inheritance or identify disruption of the resistance. Once identified, the resistance gene can be isolated by either of two approaches that have proved successful in recent years (see Staskawicz et al., Science, 68:661-67 (1995)). These are positional or map-based cloning and insertional mutagenesis or transposon tagging. Because there may be no DspE-insensitive cultivars (susceptible to *Pseudomonas* harboring *dspE*; each of four soybean cultivars tested responded to *dspE*), map-based cloning (which requires crosses between susceptible and resistant lines to identify the position of the resistance gene relative to other genes) may not be feasible. The preferred approach would more likely involve insertional mutagenesis, using the *dspE* gene or protein in

screens to identify lines which had lost the the product of *dspE* due to transposon tagging of the corresponding resistance gene.

EXAMPLES

5

Example 1 - Recombinant DNA techniques.

Isolation of DNA, restriction enzyme digests, ligation, transformation of *Escherichia coli*, and construction of and colony hybridization to screen a *P. syringae* pv. tomato DC3000 genomic library were performed as described by
10 Sambrook, et al. (Sambrook, J., et al., Molecular cloning: A Laboratory manual, (Cold Spring Harbor Laboratory, Cold Spring Harbor, NY) (1989), which is hereby incorporated by reference). The library was constructed using pCPP47 (Bauer, D. W., et al., Mol. Plant-Microbe Interact., 10:369-379 (1997), which is hereby incorporated by reference). Except where noted, *E. coli* DH5 and *E. coli* DH5 α were used as hosts
15 for DNA clones, and pBluescript or pBC plasmids (Stratagene, La Jolla, CA) were used as vectors. *E. amylovora* was transformed by electroporation as described (Bauer, D. W. in "Molecular Genetics of Pathogenicity of *Erwinia amylovora*: Techniques, Tools and Their Applications", (Ph. D. Thesis), Cornell University, Ithaca, NY (1990), which is hereby incorporated by reference). Plasmids were
20 mobilized into *E. amylovora* and *P. syringae* using pRK2013 (Figurski, D., et al., Proc. Natl. Acad. Sci. USA 76:1648-1652 (1979), which is hereby incorporated by reference).

Example 2 - Nucleotide sequencing and analysis.

25 The nucleotide sequence of the *dsp* region of *E. amylovora* strain Ea321 was determined using subclones of pCPP430 (Beer, S. V., et al., in Advances in Molecular Genetics of Plant-Microbe Interactions, Hennecke, H., et al., eds. (Kluwer Academic Publishers, Dordrecht, The Netherlands), pp. 53-60 (1991), which is hereby incorporated by reference). The nucleotide sequence of the *avrE* locus was
30 determined using subclones of pCPP2357, a clone selected from a *P. syringae* pv. tomato DC3000 genomic cosmid library based on hybridization with the *hrpRS* operon of *P. syringae* pv. *syringae*, and the finding, based on partial sequencing, that it contained the *avrE* locus. Nucleotide sequencing was performed by the Cornell

Biotechnology Sequencing Facility on a Model 377 Sequencer (Perkin Elmer/Applied Biosystems Division, Foster City, CA). Sequence assembly, analysis, and comparisons were performed using the programs of the GCG software package, version 7.1 (Genetics Computer Groups, Inc., Madison, WI) and DNASTAR (DNASTAR, Inc., Madison, WI). Database searches were performed using BLAST (Altschul, S. F., et al., Proc. Nat. Acad. Sci. USA, 87:5509-5513 (1990) which is hereby incorporated by reference).

Example 3 - Expression of DspE and DspE' in *E. coli*.

The *dspE* operon was cloned in two pieces into pCPP50, a derivative of PINIII¹¹³-A2 (Duffaud, G. D., et al. in Methods in Enzymology, Wu, R., et al., eds. (Academic Press, New York), 153:492-50 (1987), which is hereby incorporated by reference) with an expanded polylinker, yielding pCPP1259. Expression in pCPP1259 is driven by the *Ipp* promoter of *E. coli*, under the control of the *lac* operator. An intermediate clone, pCPP1244, extending from the start of the operon to the *Bam*HI site in the middle of *dspE*, also was isolated. *E. coli* DH5 α strains containing pCPP1259 and pCPP1244 were grown in LB at 37°C to an OD₆₂₀ of 0.3. Isopropylthio- β -D-galactoside then was added to 1 mM, and the cells further incubated until reaching an OD₆₂₀ of 0.5. Cells were concentrated two-fold, lysed and subjected to SDS-PAGE as previously described (Sambrook, J., et al., Molecular cloning: A Laboratory Manual (Cold Spring Harbor Laboratory, Cold Spring Harbor, NY) (1989), which is hereby incorporated by reference), using 7.5% acrylamide. Cells containing pCPP50 were included for comparison. Proteins were visualized by Coomassie staining.

Example 4 - Deletion mutagenesis of *dspE*.

1554 bp were deleted from the 5' *Hind*III-*Bam*HI fragment of *dspE* in pCPP1237 using unique *Stu*I and *Sma*I sites. The mutagenized clone then was inserted into the suicide vector pKNG101 (Kaniga, K., et al., Gene, 109:137-42 (1991), which is hereby incorporated by reference) using *E. coli* SM10 λ *pir* as a host, yielding pCPP1241. The mutation, designated Δ 1554, then was transferred into *E. amylovora* strains using marker eviction as described previously (Bogdanove, A. J.,

et al., J. Bacteriol., 178:1720-30 (1996), which is hereby incorporated by reference). 1521 bp were deleted from the 3' *HindIII* fragment of *dspE* in pCPP1246 using two *BstEII* sites blunted with Klenow fragment. This mutation, $\Delta 1521$, was transferred into *E. amylovora* strains as above.

5

Example 5 - Pathogenicity assays.

For *E. amylovora* strains, cell suspensions of 5×10^8 colony-forming units (cfu) per ml were pipetted into wells cut in immature Bartlett pear fruit, or stabbed into Jonamac apple and cotoneaster shoots, and assays carried out as described previously (Beer, S. V., in Methods in Phytobacteriology, Klement, Z., et al., eds. (Adadémiai Kiadó, Budapest), pp. 373-374 (the "1990"); Aldwinckle, H. S., et al., Phytopathology, 66:1439-44 (1976), which are hereby incorporated by reference). For *P. syringae* pv. *glycinea*, panels of primary leaves of 2-week-old soybean seedlings (*Glycine max*, cultivar Norchief) were infiltrated with bacterial suspensions of 8×10^5 cfu/ml as for the HR assay, below. Plants were then covered with clear plastic bags and incubated under fluorescent lights (16 hr/day) at 22°C for 5-7 days. Leaves were scored for necrosis and chlorosis.

20

Example 6 - HR assays.

Tobacco leaf panels (*Nicotiana tabacum* L. 'xanthi') were infiltrated with bacterial cell suspensions as described previously (Wei, Z. M., et al., Science, 257:85-88 (1992); Bauer, D. W., et al., Mol. Plant-Microbe Interact., 4:493-99 (1991), which are hereby incorporated by reference). Primary leaves of 2-week-old soybean seedlings (secondary leaves emerging) were infiltrated with bacterial cell suspensions as for tobacco. Plants were scored for HR (tissue collapse) after 24-48 hr on the laboratory bench. *E. amylovora* strains were suspended in 5 mM KPO₄ buffer, pH 6.8, and *P. syringae* strains in 10 mM MgCl₂.

25

Example 7 - GUS assays.

30

Cells were 1.) grown in LB to an OD₆₂₀ of 0.9-1.0; 2.) grown in LB to an OD₆₂₀ of 0.5, then washed and resuspended in a *hrp*-gene-inducing minimal medium (Hrp MM; Huynh, T. V., et al., Science, 345:1374-77 (1989), which is

hereby incorporated by reference) to an OD₆₂₀ of 0.2 and incubated at 21° C for 36 hr to a final OD₆₂₀ of 0.9-1.0; or 3.) grown in LB to an OD₆₂₀ of 0.5, washed and concentrated 2-fold in 5 mM KPO₄ buffer, pH 6.8, and then transferred to freshly cut wells in pear halves and incubated as for the pathogenicity assay for 36 hr. Cells were
5 assayed for β-glucuronidase (GUS) activity essentially according to Jefferson (Jefferson, R. A., Plant Molecular Biology Reporter, 5:387-405 (1987), which is hereby incorporated by reference). For the cells in LB or Hrp MM, 50 μl were mixed with 200 μl GUS extraction buffer (50 mM NaHPO₄, pH 7.0, 10 mM
β-mercaptoethanol, 10 mM Na₂EDTA, 0.1% sodium lauryl sarcosine, 0.1% Triton
10 X-100) containing 2 mM 4-methylumbelliferyl β-D-glucuronide as substrate and incubated at 37° C for 100 min. For cells in pear fruit, the tissue surrounding the well was excised using a #4 cork borer and homogenized in 5 mM KPO₄ buffer, pH 6.8. 200 μl of homogenate was mixed with 800 μl of GUS extraction buffer with substrate and incubated as above. Reactions were stopped by adding Na₂CO₃ to a final
15 concentration of 0.2 M in a total volume of 2 ml. Fluorescence was measured using a TKO 100 Mini-Fluorometer (Hoefer Scientific Instruments, San Francisco, CA). For all samples, cell concentration was estimated by dilution plating, and fluorometric readings were converted to pmole of substrate hydrolyzed/10⁸ cfu/min, after Miller (Miller, J. H., A Short Course in Bacterial Genetics: A Laboratory Manual and
20 Handbook for Escherichia coli and Related Bacteria (Cold Spring Harbor Laboratory Press, Plainview, NY) (1992), which is hereby incorporated by reference).

Example 8 - The "disease-specific" (dsp) region of *E. amylovora* consists of a 6.6 kb, two-gene operon.

25 Mapping of previous transposon insertions (Steinberger, E. M., et al., Mol. Plant-Microbe Interact., 1:135-44 (1988), which is hereby incorporated by reference) that abolish pathogenicity but not HR-eliciting ability confirmed the presence of the "disease specific" (dsp) region downstream of the *hrpN* gene in strain Ea321 as reported in strain CFBP1430 (Barny, A. M., et al., Mol. Microbiol., 4:777-
30 86 (1990), which is hereby incorporated by reference). The sequence of approximately 15 kb of DNA downstream of *hrpN* from Ea321 was determined, revealing several open reading frames (ORFs' Fig. 1). One ORF, in an apparent 6.6 kb operon with a

a smaller ORF, spanned the area to which the *dsp* insertions mapped. These two ORFs were designated *dspE* and *dspF*, ~~and the operon, *dspE*~~. *dspE* is preceded (beginning 70 bp upstream of the initiation codon) by the sequence GGAACCN₁₅CAACATAA (SEQ. ID. No. 5), which matches the HrpL-dependent promoter consensus sequence or "hrpbox" of *E. amylovora* (Kim, J. H., et al., *J. Bacteriol.*, 179:1690-97 (1997); Kim, J. H., et al., *J. Bacteriol.*, 179:1690-97 (1997), which are hereby incorporated by reference) and strongly resembles the *hrp* box of *P. syringae* *hrp* and *avr* genes (Xiao, Y., et al., *J. Bacteriol.*, 176:3089-91 (1994), which is hereby incorporated by reference). Immediately downstream of *dspF* is A/T-rich DNA, followed by an ORF (ORF7) highly similar to the *Salmonella typhimurium* gene *spvR*, a member of the *lysR* family of regulatory genes (Caldwell, A. L. & Gulig, P. A., *J. Bacteriol.*, 173:7176-85 (1991), which is hereby incorporated by reference). Immediately upstream of the *dspE* operon is a Hrp-regulated gene, *hrpW*, encoding a novel harpin.

The deduced product of *dspE* contains 1838 amino acid residues and is hydrophilic. The predicted molecular weight, 198 kD, was confirmed by expression in *E. coli* (Fig. 2). Expression of an intermediate clone containing only the 5' half of *dspE* yielded a protein of corresponding predicted mobility, suggesting that the N-terminal half of the protein might form an independently stable domain. DspF, predicted to be 16 kD, acidic (pI, 4.45), and predominantly α -helical, with amphipathic α helices in its C-terminus, is physically similar to virulence factor chaperones of animal-pathogenic bacteria (Wattiau, P., et al., *Mol. Microbiol.*, 20:255-62 (1996), which is hereby incorporated by reference).

Example 9 - *dspE* is required for fire blight.

Two in-frame deletions within *dspE* (Fig. 1) were made in Ea321 and Ea273 (low- and high-virulence strains, respectively). The first (Δ 1554) corresponds to amino acid residues G₂₀₃ to G₇₂₀, and the second (Δ 1521) to amino acid residues T₁₀₆₄ to V₁₅₇₀. Each deletion abolished the ability of both strains to cause fire blight when inoculated to immature pear fruit (Fig. 3), apple shoots, or cotoneaster shoots. Δ 1554 was complemented by a clone carrying only the overlapping 5' half of *dspE*, further suggesting that the N-terminus of the protein forms a stable domain (Figs. 1 and 3).

5

10

25

20

30

Ea273 in *hrp* MM was two orders of magnitude lower than that in *HrpL* + strains. Data for Ea273 and derivatives are shown in Fig. 4.

Example 12 - *dspE* and *dspF* are homologous with genes in the *avrE* locus of *Pseudomonas syringae* pv. tomato.

5 A BLAST (Altschul, S. F., et al., J. Mol. Biol., 215:403-10 (1990), which is hereby incorporated by reference) search of the genetic databases revealed similarity of *dspE* to a partial sequence of the *avrE* locus of *P. syringae* pv. tomato (Lorang, J. M., et al., Mol. Plant-Microbe Interact., 8:49-57 (1995), which is hereby
10 incorporated by reference). A cosmid library of *P. syringae* pv. tomato DC3000 genomic DNA was constructed, and a clone overlapping the *hrp* gene cluster and containing the *avrE* locus was isolated (pCPP2357). The complete nucleotide sequence of the *avrE* locus was determined, revealing the homolog of *dspE* (encoding
15 a 195 kD, 1795 amino acid protein of 30% identity) alone in an operon previously designated transcription unit III, and a homolog of *dspF* (encoding a 14 kD, a 129 amino acid protein of 43% identity) at the end of the juxtaposed and opposing operon previously designated transcription unit IV (Fig. 1). These genes are designated *avrE* and *avrF*. The C-terminal half of the DspE and AvrE alignment (from V₈₄₅ of DspE) shows greater conservation (33% identity) than the N-terminal half (26% identity).
20 AvrE contains a motif (aa residues A₄₅₀ to T₄₅₇) conserved in ATP- or GTP-binding proteins ("P-loop"; Saraste, M., et al., Trends Biochem. Sci., 15:430-34 (1990), which is hereby incorporated by reference). This motif is not conserved in DspE, however, and its functional significance in AvrE, if any, is unclear. Amino acid identities are distributed equally throughout the DspF and AvrF alignment, and AvrF shares the
25 predicted physical characteristics of DspF. Upstream of *avrF*, ^{completing} ~~completing~~ the operon, is a 2.5 kb gene with no similarity to sequences in the genetic databases.

Example 13 - The *dspE* operon functions as an avirulence locus.

The *dspE* operon was cloned into pML 122 (Labes, M., et al., Gene,
30 89:37-46 (1990), which is hereby incorporated by reference) downstream of the *nptII* promoter, and this construct, pCPP1250, was mobilized into *P. syringae* pv. glycinea race 4. The resulting strain, but not a control strain containing pML 122, elicited the HR in soybean cultivars Acme, Centennial, Harasoy, and Norchief; in Norchief plants

incubated under conducive conditions, race 4 harboring pCPP1250 failed to cause symptoms of disease, while the control strain caused necrosis and chlorosis that spread from the point of inoculation (Fig. 5).

5 **Example 14 - *avrE* complements *dspE* mutations.**

Cosmid pCPP2357 was mobilized into Ea321 *dspE* mutant strains Δ 1554 and Δ 1521. The resulting transconjugants were pathogenic but low in virulence. Ea321*dspE* Δ 1521 carrying pCPP2357 with a transposon insertion in the *avrE* gene was non-pathogenic, demonstrating that the complementation observed
10 was *avrE*-specific (Figs. 1 and 5). The same results were observed for transconjugants of the Ea273*dspE* Δ 1521 mutant.

Over thirty bacterial *avr* genes have been discovered. The plethora of *avr* genes is thought to result from an "evolutionary tug-of-war" (Dangl, J. L., in Bacterial Pathogenesis of Plants and Animals: Molecular and Cellular Mechanisms
15 (Current Topics in Microbiology and Immunology), Dangl, J. L., ed. (Springer, Berlin), 192:99-118 (1994), which is hereby incorporated by reference), a reiterative process of selection, counterselection due to *R* genes, and modification or substitution of *avr* genes that was originally discerned by Flor, who hypothesized that "during
20 their parallel evolution host and parasite developed complementary genic systems" (Flor, H. H., Adv. Genet., 8:29-54 (1956), which is hereby incorporated by reference). However, only a few *avr* genes (including *avrE* in strain PT23) play detectable roles in virulence or pathogen fitness in their native genetic background (Lorang, J. M., et al., Mol. Plant-Microbe Interact., 7:508-15 (1994); Kearney, B., et al., Nature,
25 346:385-86 (1990); Swarup, S., et al., Phytopathology, 81:802-808 (1991); De Feyter, R. D., et al., Mol. Plant-Microbe Interact., 6:225-37 (1993); Ritter, C., et al., Mol. Plant-Microbe Interact., 8:444-53 (1995), which are hereby incorporated by reference), and the selective force driving the maintenance in pathogen genomes of many of these host-range-limiting factors has remained a mystery. It is now clear, though, that several Avr proteins are delivered into plant cells by the Hrp pathway
30 (Gopalan, S., et al., Plant Cell, 8:1095-1105 (1996); Tang, X., et al., Science, 274:2060-63 (1996); Scofield, S. R., et al., Science, 274:2063-65 (1996); Leister, R. T., et al., Proc. Natl. Acad. Sci. USA, 93:15497-15502 (1996); Van Den Ackerveken,

G., et al., Cell, 87:1307-16 (1996), which are hereby incorporated by reference) and, therefore, are likely to be fundamentally virulence factors, which interact (directly, or indirectly through enzymatic products) with host targets to promote parasitism.

5 Mutation of such targets (selected because of reduced susceptibility) as well as the evolution of R proteins that recognize the Avr proteins would force the acquisition or evolution of new or modified Avr proteins and result in the proliferation of *avr* genes. Cumulatively, these co-evolutionary processes likely would drive a trend toward *avr* genes with quantitative and redundant effects in pathogenesis rather than critically important roles (Alfano, J. R., et al., Plant Cell, 8:1683-16988 (1996), which is hereby
10 incorporated by reference).

It has been found that the homologs *dspE* and *avrE* contribute to disease to dramatically different extents. The avirulence locus can substitute transgenerically for the pathogenicity operon, and that the avirulence function of *dspE* extends across pathogen genera as well. These findings support the hypothesis that
15 *avr* genes have a primary function in disease. Moreover, they support and expand the coevolutionary model for *avr* gene proliferation discussed above, and they have practical implications concerning the control of fire blight and other bacterial diseases of perennials.

One can predict from the model that the relative contribution to
20 pathogenicity of a particular factor would reflect, in part, the genetic history of the pathogen, specifically, the degree of co-evolution with its host(s). *dspE* is required for pathogenicity; *avrE* has a quantitative, strain-dependent, virulence phenotype. Consistent with the prediction, evolution of corresponding R genes and modification of targets of pathogen virulence factors is likely to have occurred more often and to a
25 greater extent over time in the herbaceous hosts typically infected by *P. syringae* pathovars than in the woody hosts with which *E. amylovora* presumably evolved. Alternatively or additionally, acquisition of *dspE* (through evolution or horizontal transfer) by *E. amylovora* could have occurred relatively more recently than acquisition of *avrE* by *P. syringae*, allowing less time for coevolution leading to
30 modification or the development of redundant function.

One could also hypothesize from the model that virulence factors may be conserved among pathogens, yet individually adapted to avoid detection on a

particular host. Preliminary results from Southern blot hybridizations suggest that *P. syringae* pv. *glycinea* harbors an *avrE* homolog, which, if functional, would support such a hypothesis. Similarly, homologs of the soybean cultivar-specific genes *avrA* and *avrD* from *P. syringae* pv. *tomato* exist in *P. syringae* pv. *glycinea* (Kobayashi, D. Y., et al., Proc. Natl. Acad. Sci. USA, 86:157-161 (1989), which is hereby incorporated by reference).

The homology and abilities of *dspE* and *avrE* to function transgenerically expand the model for *avr* gene proliferation. Major components of an evolution toward multifactor virulence could be procurement of genes encoding novel virulence factors from heterologous pathogens, and conservation of a functionally cosmopolitan virulence factor delivery system (and possibly conservation of a universal Hrp-pathway-targeting signal on the factors themselves) that would enable their deployment. Indeed, many *avr* genes are on plasmids and scattered in their distribution among pathogen strains (Dangl, J. L., in Bacterial Pathogenesis of Plants and Animals: Molecular and Cellular Mechanisms (Current Topics in Microbiology and Immunology), Dangl, J. L., ed. (Springer, Berlin), 192:99-118 (1994), which is hereby incorporated by reference), and individual *hrp* genes are conserved and even interchangeable (Arlat, M., et al., Mol. Plant-Microbe Interact., 4:593-601 (1991); Laby, R. J., et al., Mol. Plant-Microbe Interact., 5:412-19 (1992), which is hereby incorporated by reference). The presence of *dspE* and *avrE* in distinct genera suggests horizontal transfer of an ancestral locus, and, although *dspE* and *avrE* are homologous and *hrp*-linked, the transgeneric function of these genes suggests that the Hrp pathways in *E. amylovora* and *P. syringae* have remained insensitive to differences accrued in DspE and AvrE over evolution. It is predicted that even non-homologous Avr-like proteins will function across phytopathogenic bacterial genera.

It remains to be shown whether the avirulence function of the *dspE* locus is Hrp-pathway-dependent. This seems likely, and it will be important to determine the localization of the *dspE* and *dspF* gene products in the plant-bacterial interaction. The physical similarity of DspF (and AvrF) to chaperones required for type III secretion of virulence factors from animal-pathogenic bacteria (Wattiau, P., et al., Mol. Microbiol., 20:255-62 (1996), which is hereby incorporated by reference) is

intriguing and novel in phytopathogenic bacteria. The requirement of these chaperones appears to be due to a role other than targeting to the secretion pathway (Woestyn, S., et al., Mol. Microbiol., 20:1261-71 (1996), which is hereby incorporated by reference): chaperones may stabilize proteins, maintain proteins in an appropriate conformation for secretion, or prevent premature polymerization or association with other proteins. Perhaps, DspF binds to DspE (and AvrF to AvrE) and plays a similar role, which might be particularly important for the latter protein due to its large size and probable multidomain nature.

The *dspE* operon is the first described avirulence locus in *E. amylovora*. A homolog of *avrRxx* from *Xanthomonas campestris* (Whalen, M. C., et al., Proc. Natl. Acad. Sci. USA, 85:6743-47 (1988), which is hereby incorporated by reference) has been found near the *dspE* operon (Kim, J. F., in Molecular Characterization of a Novel Harpin and Two hrp Secretory Operons of Erwinia amylovora, and a *hrp* Operon of *E. chrysanthemi* (Ph.D. Thesis), Cornell University, Ithaca, NY (1997)). Monogenic (*R*-gene-mediated) resistance to fire blight has not been reported, but differential virulence of *E. amylovora* strains on apple cultivars has been observed (Norelli, J. L., et al., Phytopathology, 74:136-39 (1984), which is hereby incorporated by reference). Also, some strains of *E. amylovora* infect *Rubus* spp. and not pomaceous plants, and vice-versa (Starr, M. P., et al., Phytopathology, 41:915-19 (1951), which is hereby incorporated by reference). Whether the *dspE* operon and the *avrRxx* homolog or other potential elicitors play a role in these specificities should be determined.

Although the *dspE* operon triggers defense responses in soybean when expressed in *P. syringae* pv. *glycinea*, it is not required for the HR of soybean elicited by *E. amylovora*. Neither is *hrpN* required (Fig. 3). It is possible that *E. amylovora* must have one or the other, *dspE* or *hrpN*, to elicit the HR in soybean. It has been observed, however, that purified harpin does not elicit the HR in soybean, suggesting the alternative explanation that *E. amylovora* harbors another *avr* gene recognized by this plant.

Recognition of *E. amylovora* avirulence signals in soybean indicates the presence of one or more *R* genes that might be useful for engineering fire blight resistant apple and pear trees. *R*-gene-mediated resistance to the apple scab pathogen

Venturia inaequalis (Williams, E. B., et al., Ann. Rev. Phytopathol., 7:223-46 (1969), which is hereby incorporated by reference) and successful transformation of apple with attacin E for control of fire blight (Norelli, J. L., et al., Euphytica, 77:123-28 (1994), which is hereby incorporated by reference) attest the feasibility of such an approach. *R* gene-mediated resistance to apple scab has been overcome in the field (Parisi, L., et al., Phytopathology, 83:533-37 (1993), which is hereby incorporated by reference), but the requirement for *dspE* in disease favors relative durability of a *dspE*-specific *R* gene (Kearney, B. et al., Nature, 346:385-86 (1990), which is hereby incorporated by reference). Avirulence screening of *dspE* and other *E. amylovora* genes in pathogens of genetically tractable plants such as *Arabidopsis* could broaden the pool of candidate *R* genes and hasten their isolation. A similar approach could be used to isolate *R* genes effective against other diseases of woody plants. Furthermore, if the *dspE* operon is as widely conserved as is suggested by its homology with the *avrE* locus, a corresponding *R* gene could be effective against a variety of pathogens both of woody and herbaceous plants.

Native (non-denatured) DspE protein has not been produced in sufficient quantity to test its ability to elicit the HR (i.e. hypersensitive response) in a manner similar to hypersensitive response elicitors (i.e., by exogenous application). Therefore, no one has shown that *dspE* of *E. amylovora* elicits the HR when applied to plants as an isolated cell-free material. However, when the gene encoding the protein is transferred to another bacterium (along with the smaller *dspF* gene), e.g., *Pseudomonas syringae*, which ordinarily causes disease on certain plants, the recipient bacterium no longer causes disease but instead elicits the HR. The mechanism for this is not known for sure, but it is suspected to involve (and there is compelling evidence for) a mechanism in which the bacterial cell actually injects the DspE protein into the living plant cell, triggering the development of plant cell collapse (i.e. HR). Presumably, when the DspE protein is in the living plant cell, it might signal the plant to develop resistance to insects and pathogens.

Based on the similarity of the predicted physical characteristics of DspF to those of known chaperone proteins from animal pathogens, it is believed that this rather small protein is a chaperone of DspE. Chaperones in animal pathogens bind in the cytoplasm to specific proteins to be secreted. They seem to be required for

secretion of the proteins but are not themselves secreted. Evidence suggests that the chaperones are not involved directly in targeting the secreted proteins to the secretion apparatus. Instead, they may act to stabilize the proteins in the cytoplasm and/or prevent their premature aggregation or association with other proteins (e.g., bacterial proteins that direct transport through the host cell-membrane).

5 The *dspE* gene bears no similarity to known genes except *avrE*.
Enzymatic function (i.e., one resulting in the production of a secondary molecule that elicits the HR) of *DspE* cannot be ruled out at present. In fact, one *avr* gene product is known to elicit HR indirectly by catalyzing synthesis of a diffusible elicitor molecule.
10 However, the simplest explanation for the observed HR eliciting function of the *dspE* operon expressed in *Pseudomonas* species is that the protein encoded by the *dspE* gene is secreted from the bacterium and possibly transported into the plant cell, that there it triggers directly plant defense responses leading to the HR, and that this process is mediated by a specific resistance gene product that recognizes (acts as a
15 receptor of) the *DspE* protein. Indeed, four *avr* genes that depend on the Hrp secretory apparatus to function when expressed in bacteria have been shown to cause HR when expressed transgenically within plant cells. One of these has been shown to encode a protein that directly interacts with the product of its corresponding resistance gene. Ultimately, whether *DspE* elicits plant defense responses from outside or inside
20 the plant cell, directly or through a secondary molecule, must be determined in order to define practical applications of this protein and its encoding gene as a plant defense elicitor.

Although the invention has been described in detail for the purpose of illustration, it is understood that such detail is solely for that purpose, and variations
25 can be made therein by those skilled in the art without departing from the spirit and scope of the invention which is defined by the following claims.
